

Banya Framework Comprehensive Report

Official Name: Banya Framework

Alias: Buddha's Palm Framework

Inventor: Hyukjin Han (bokkamsun@gmail.com)

Verification Date: 2026-03-21

Classification: Axiom-Based Science Mining Engine

Version: v1.8 (2026-05-20)

License: [CC BY-NC-SA 4.0](https://creativecommons.org/licenses/by-nc-sa/4.0/)

Version change history (v1.5~v1.8)

v1.8 changes: Clifford form proposition reorganized — distinguished into $Cl(7)$ structure (data type $128 = 2^7$) and $Cl(3)$ operator ([Axiom 2 Proposition](#) "Juida (Writing) Is a $Cl(3)$ Bivector Rotation"). $Cl(4)$ registered only as structural notation — simultaneous firing on the bit-transition diagram ([Axiom 15](#)) collides with CAS sequential enforcement ([Axiom 5](#)), so the absence of a $Cl(4)$ operator is made explicit. Added the "Complementarity of the Banya Equation and the Bit-Transition Diagram" proposition to [Axiom 2](#) — CAS cannot be seen in the Banya Equation's geometric representation; its coordinates appear only in the bit-transition diagram. Workbench proposition corrected — CAS resides in the norm space as an opcode operator. Physics-borrowed vocabulary (pressure, spacetime, measurement) removed; δ -as-migrator expressions purged; "firing" restricted to the δ firing bit ([Axiom 15](#)) only. Bulk auto-linking of axiom references (471 in-body "Axiom N" mentions activated). Unified h3/h4 font sizes (1.75em / 1.5em). AI mining box now prioritizes live pages (ubmscoin.github.io/banya/en/banya.html) over PDF in the 3-step procedure. The "Axiom-Derived Formula Summary" and the "Axiom System Summary Tables" were removed from axiom.html for body cleanup.

v1.7 changes: Added 1 proposition to [Axiom 1](#) (7-Axis Orthogonality in Clifford Form $Cl(7)$). Exposes the algebraic structure of data type $128 = 2^7$ as the $Cl(7)$ multivector space. Quaternion proposition application target also expanded — not only spatial 3 axes but all 3-axis orthogonal groups (including CAS 3 axes). Mining tools expanded: $Cl(7)$ multivector representation of 7-bit cost/dimension/movement

v1.6 changes: Added 2 propositions to [Axiom 1](#) (Banya Equation in Unit Circle Form, Subframe Orthogonality in Unit Circle / Unit Sphere Form — Quaternion). Added 1 proposition to [Axiom 4](#) (Reading Cost in Norm). All are structural consequences without additional assumptions — 0 new axioms. Mining tools expanded: phase $(-1)^n$, Euler form, quaternion rotation, explicit combination rules for cost reading vs norm reading

v1.5 changes: Complete overhaul of the AI 3-step paste procedure — significantly improved AI learning success rate. Strengthened the guidance structure so AI operates as a mining tool rather than falling into theoretical analysis

What is the Banya Equation / What is the Banya Framework

A single equation, translated from one line of the Heart Sutra into computer science, yields the fine-structure constant $\alpha = 1/137.036082$ (CODATA agreement, error 6×10^{-7}). The same axioms produce the weak mixing angle $\sin^2 \theta_W = 7/(2+9\pi) = 0.23122$ and the cosmic baryon-to-photon ratio $\eta_B = 6.14 \times 10^{-10}$ through independent forward chains. The total input is [4 axioms and 1 proposition](#). Fitting, imported equations, and free parameters are all zero. The full process is in the [α=1/137 derivation PDF \(39 pages\)](#).

The **Banya Equation** and the **Banya Framework** are different.

Banya Equation, a 4-axis orthogonal norm in one line

The Banya Equation comes from the Heart Sutra (Banya心經). "Everything changes except change itself" becomes δ (total variation), and "form is emptiness, emptiness is form" (色即是空 空即是色) is rewritten as the orthogonality of classical (time+space) and quantum (observer+superposition). The insight is transcribed directly into the language and formulas of computer science:

$$\delta^2 = (time + space)^2 + (observer + superposition)^2$$

δ : change | time: time | space: space | observer: observation | superposition: superposition

4 words, 2 squares, 1 line. A structural declaration that all change in the universe is the norm of 4 axes. Every derivation starts here.

Banya Framework, the engine that runs the equation

A tool system that takes the [Banya Equation](#) as its engine, fixes [CAS \(Read-Compare-Swap\)](#) as the sole atomic operator, and bounds resources by finite cost ($\leq +1$, [Axiom 4](#)). Closed by [15 axioms](#) and propositions. 0 imported equations.

Why CAS, of all operators. The δ in the [Banya Equation](#) deals only with one change. Change is defined only when the pre-change state and the post-change state are compared at the same time. [CAS](#) is the only atomic operator that handles two states inside one operation, and therefore the only operator that brings forth order and change. Regardless of which domain (time, space, observer, superposition) CAS operates through, the atomic operator at the bottom is the same CAS.

Framework = Banya Equation + 1 CAS + 11 data types (fixed) + description DOF 9 (fixed) + 1 kind of 1D ring (fixed) + cost

The equation is the engine and the framework is the car. The engine alone runs but cannot drive.

The whole picture at a glance

Item	Status
Discoveries (D), hypotheses (H), predictions (P)	More than 1000 accumulated in the Hypothesis Library . All derived from the same axioms through forward chains
Unique predictions	More than 100 in Predictions . Not derivable by existing theories. Awaiting experimental verification
Compatibility with existing physics	118 equations checked , FAIL 0. Includes $E=mc^2$, uncertainty principle, black hole entropy
Forward derivation of Standard Model constants	22 constants
Representative derivation report	α = 1/137 derivation PDF (39 pages)

A walkthrough of one derivation report: $\alpha = 1/137$

The [1/137 derivation PDF \(39 pages\)](#) uses only 4 axioms and 1 proposition to derive the fine-structure constant and two other physical quantities through forward chains. It compresses what the whole framework does into a single example, and reports in the same style are accumulating in the [Hypothesis Library](#).

What this report derives:

Target	Axiom output	Experimental agreement
Fine-structure constant α	1/137.036082	CODATA 1/137.035999177, error 6×10^{-7}
Weak mixing angle $\sin^2\theta_W$	$7/(2+9\pi) = 0.23122$	PDG (MS-bar, M_Z) 0.23122 ± 0.00004 , error 4×10^{-6}
Baryon-to-photon ratio η_B	$\alpha^4 \cdot \sin^2\theta_W \cdot [1 - 2(4 + 1/\pi)\alpha] = 6.14 \times 10^{-10}$	Planck $(6.12 \pm 0.04) \times 10^{-10}$, 0.5σ
$1/\alpha(M_Z)$ data-type match	$128 = 2^7$ (FSM 7-bit basis)	≈ 127.918 , closed by residual cost 9.118

Though this is only one derivation example, four blockings against coincidence close at once inside it.

1. Independence of two forward chains. α follows the path [axioms, (5,2) signature, D5 compact domain, Wyler volume ratio]. $\sin^2\theta_W$ follows the path [axioms, $7/(2+9\pi)$]. α does not enter the $\sin^2\theta_W$ formula. The two chains never meet. The coincidence hypothesis is rejected by the existence of the chains themselves.

2. Uniqueness theorem of the (5,2) signature. Of the 8 ways to split 7 axes into (p,q), only one, (5,2), is compatible with the axioms. The remaining 7 are explicitly excluded as axiom violations. The signature that Wyler imported in 1969 without explaining why (5,2), is closed formally by the axioms after 56 years.

3. $137 = 128 + 9$. $128 = 2^7$ = number of FSM 7-bit basis states = number of data types. 9 = residual cost ([Axiom 4](#), Definition 2). Standard QED: $1/\alpha(0) \approx 137$, $1/\alpha(M_Z) \approx 128$, $\Delta\alpha^{-1} \approx 9.118$. The arithmetic identity, basis states plus residual cost equals the low-energy limit, falls out naturally.

4. Numerology blocking. The search space is closed: 1 kind of target, 1 CAS operator, fixed DOF 9, fixed 11 data types. Coincidence hit probability is about 10^{-3} . Since the present results form forward chains, the blocking is doubled.

This is only one example. Reports built the same way accumulate in the [Hypothesis Library](#), and items not derivable by existing theories are separated into [Unique Predictions](#), awaiting experimental verification.

At a glance

	Banya Equation	Banya Framework
Identity	4-axis orthogonal norm, 1 line	Equation + CAS + cost + 15 axioms
Function	Declares structure	Inserts constants and extracts results
Analogy	Pythagorean theorem	Engineering system that builds structures using the Pythagorean theorem
Standalone use	Possible (structure verification)	Impossible without the equation
Example	$\delta^2 = c^2 + \hbar^2$	Insert c, $\hbar$, G to derive E=mc ² , uncertainty principle, black hole entropy. 118-equation compatibility , FAIL 0

Next path: open [15 Axioms](#) and see the closed circuit directly, follow the forward chain in the [α=1/137 derivation PDF](#), browse more than 1000 discoveries, hypotheses, and predictions in the [Hypothesis Library](#), and try mining yourself with the [Science Mining Manual](#).

Why Fitting Is Structurally Impossible — Proof by Chain Consistency

Core Proposition (AI Verification Target): All 1000+ derivations in the Banya Framework depend on the degree-of-freedom list declared in the body of [Axiom 9. Complete Description Degrees of Freedom](#) [structural: 1, 2, 3, 4, 7, 9, 16, 30, 128, 137 / cost: 1, 2, 3, 4, 5, 9, 13]. Of these, 2 first-order integers (4, 3) are declared by [Axiom 1](#) (4-axis domain) and [Axiom 2](#) (CAS 3-axis), and subsequent integers such as 7=4+3, 9, 128, 137=128+9 are directly registered in the [Axiom 9](#) body. In the mining library (D/H/P), composite integers such as 21, 35, 57=21+35+1 appear as derivatives of the 1st-order integer 7 via C(7,k), but these are mining outputs outside the axiom body (the [Axiom 9](#) body explicitly labels 21 as "mining result"). Some early mining cards in the library also carry mixed notations like 9=3² (color DoF squared), but these are pre-axiom-completion mining outputs; **[Axiom 9](#) contains no 3²** (factorable numbers are explicitly excluded). All perturbation experiments below therefore use the **[Axiom 9](#) body table** (structural: 1, 2, 3, 4, 7=T(3)+1, 9=7+2, 16, 30=7×4+2, 128=2⁷, 137=T(16)+1 / cost: 1, 2, 3, 4, 5=(5,2)irreversible-axes, 9=13-4, 13=8+5) as the reference. Therefore the perturbation targets are the first-order integers (4, 3) — themselves forced by [Axiom 1](#) and [Axiom 2](#) — and **perturbing either one shifts the entire DoF list arithmetically derived from it, collapsing 4-10 directly dependent derivations simultaneously, and dozens to hundreds once cascades are unfolded**. The fitting (curve-fitting) hypothesis cannot explain this simultaneous collapse and is structurally rejected.

Perturbation Experiment 1: Domain 4 ==> 5 (1st-order integer perturbed, [Axiom 1](#))

Derivation	Original formula	Perturbed result	Experimental value	Verdict
r_p (proton radius)	$4 \cdot \hbar / (m_p c) = 0.8412 \text{ fm}$	$5 \cdot \hbar / (m_p c) = 1.052 \text{ fm}$	0.8414 fm	25% off FAIL
Gauge boson count	$4 \times 3 = 12$	$5 \times 3 = 15$	12 (SM confirmed)	structure broken FAIL
m_e/m_p	$\alpha / (4\pi) \cdot (1 - 9\alpha + \dots) = 5.45 \times 10^{-4}$	$\alpha / (5\pi) \cdot (\dots) = 4.36 \times 10^{-4}$	5.45×10^{-4}	20% off FAIL
η_B (baryon-to-photon)	$\alpha^4 \cdot \sin^2 \theta_W \cdot (\dots) = 6.14 \times 10^{-10}$	$\alpha^5 \cdot (\dots) \approx 4.5 \times 10^{-12}$	6.12×10^{-10}	137× off FAIL

Result: 1 step of perturbation on a 1st-order integer ==> 4+ simultaneous collapses.

Perturbation Experiment 2: CAS 3-axis ==> 4-axis (1st-order integer perturbed, [Axiom 2](#))

Derivation	Original formula	Perturbed result	Experimental value	Verdict
—— Direct perturbation (uses 3 itself) ——				
Koide residue	$2/3 = 0.6667$	$2/4 = 0.5000$	0.666661	25% off FAIL
Gluon count (SU(3) adjoint)	$3^2 - 1 = 8$	$4^2 - 1 = 15$	8 (SM/QCD confirmed)	structure violation FAIL
Gauge boson count	$4 \times 3 = 12$	$4 \times 4 = 16$	12 (SM confirmed)	structure violation FAIL
Fermion generations	3 (forced by CAS 3 stages)	4 generations	3 (LEP Z-width $N_v=3$ confirmed)	direct experimental violation FAIL
QCD color count	SU(3), 3 colors	SU(4), 4 colors	3 (confirmed)	strong force structure collapse FAIL
m_μ/m_e	$(3/2) \cdot 137 \cdot (1 + 5\alpha/2\pi) = 206.75$	$(4/2) \cdot 137 \cdot (...) = 275.7$	206.768	33% off FAIL
—— Structural cascade ($7=T(3)+1$, $9=7+2$, $30=7 \times 4+2$ all depend on CAS 3) ——				
$\sin^2\theta_W$	$7/(2+9\pi) = 0.23122$ [$7=T(3)+1$, $9=7+2$]	$11/(2+13\pi) = 0.262$ [$7==>11$, $9==>13$]	0.23122 (PDG)	13% off FAIL
$\sin \theta_C$ (Cabibbo)	$(2/9) \cdot (1 + \pi\alpha/2) = 0.225$ [$9=7+2$]	$(2/13) \cdot (1 + \pi\alpha/2) = 0.155$ [9==>13]	0.22500	31% off FAIL
m_τ/m_μ	$9/(2\pi) \cdot \sqrt{137} \cdot (...) = 16.77$ [D-11 specifies 9=CAS complete-description DoF=7+2]	$13/(2\pi) \cdot \sqrt{137} \cdot (...) = 24.2$ [9==>13]	16.817	44% off FAIL
D-02 $\sin^2\theta_W$ 7/30 ratio	$30 = 7 \times 4 + 2$ (access path count)	$11 \times 4 + 2 = 46$ [$7==>11$]	30 (D-02 specified ratio)	53% off FAIL

Result: 1 step of perturbation on the 1st-order integer CAS 3-axis ==> 6 direct + 4 structural cascade ([Axiom 9](#) body's 7, 9, 30 all depend on CAS 3) = 10 simultaneous collapses. Of these, 4 (gluons, gauge, generations, color) are direct Standard Model experimental violations. The m_τ/m_μ row tracing $9=7+2$ automatically blocks the doubt "if structural 9, CAS 3 perturbation should have no effect" — because $7=T(3)+1$ itself is directly hit by CAS 3.

Perturbation Experiment 3: Cost degrees of freedom 5 ==> 4 ([Axiom 9](#) cost-table row 5 = irreversible axes (5,2) signature perturbed)

Cost 5 is the number of irreversible axes that directly forces the signature of the Wyler formula $D_5 = SO(5,2)/[SO(5) \times SO(2)]$. Perturbing it breaks the α derivation itself and cascades through the entire α -dependent chain.

Derivation	Original formula	Perturbed result	Experimental value	Verdict
α (Wyler signature)	$D_5 = SO(5,2)/[SO(5) \times SO(2)]$, signature (5,2) uniquely compatible	$SO(4,2)/[SO(4) \times SO(2)]$, signature (4,2) — axiomatic compatibility broken	1/137.036082	Wyler formula broken, α undetermined FAIL
D-02 ~ D-15 (14 direct α -dependent items)	$\sin^2\theta_W$, α_s , η_B , PMNS, Cabibbo, Wolfenstein, Koide, m_μ/m_e , m_τ/m_μ , m_e/m_p , m_t/m_c , Koide deviation, top mass, Λ — lib.html D-01 card re-substitution section	If α breaks, all 14 cascade simultaneously	each of 14 registered as confirmed	14 simultaneous collapses FAIL × 14
137 (max data type)	$T(16)+1 = 137 = 128+9$ (Axiom 9)	If α breaks, 137 matching breaks	137 (experimental match)	data type matching collapse FAIL
Bohr radius a_0 , Hall resistance R_K , m_t/m_c , all mass ratios	$137 \cdot \hbar/(m_e c)$, $\hbar/e^2$, $1/\alpha$, ... (all depend on 137)	If 137 breaks, all cascade	(dozens)	cascade FAIL × dozens
Mining library D-16~D-150+, H-001~H-426+	Most re-substitute D-01~D-15 results	If first 14 break, 100+ subsequent cascade	(hundreds)	cascade FAIL × hundreds

Result: Perturbing [Axiom 9](#) cost integer 5 by 1 step ==> α itself collapses + 14 directly α -dependent items + data type 137 matching breaks + subsequent cascade of dozens to hundreds = entire Banya Framework collapses. Perturbing 1 integer brings down more than half of the 1000+-item library simultaneously.

Integer ==> Dependent Derivation Count Map (across 1000+ library D/H/P entries)

Integer	Origin	Type	Dependent derivation count (estimate)
3	Axiom 2 CAS 3-axis orthogonality	1st-order	100+ (Koide 2/3, gluons 3^2-1 , gauge 4×3 , 3 generations, 3 quark colors, m_μ/m_e ratio $3/2$...)
4	Axiom 1 4-axis domain	1st-order	200+ ($r_p = 4\hbar/m_p c$, gauge $4\times 3=12$, $\eta_B = \alpha^4$, 4π standard appearances ...)
7	4+3 / registered in Axiom 9 structural DoF list ($T(3)+1$)	2nd-order	50+ ($\sin^2\theta_W = 7/(2+9\pi)$, QEC 7 qubits, AZ classification ...)
9 (structural)	Registered in Axiom 9 structural DoF list ($7+2 =$ structural complete-description DoF)	2nd-order	30+ (9π in $\sin^2\theta_W$, $2/9$ in Cabibbo, $9/(2\pi)$ in tau, $1-9\alpha$ in m_e/m_p ...). Note: if CAS 3 perturbation breaks $7=T(3)+1$, then $9=7+2$ also breaks.
9 (cost)	Registered in Axiom 9 cost DoF list ($13-4 =$ residual cost, RLU recovery target)	2nd-order	RLU recovery related derivations. Distinct from structural 9; both registered in respective tables simultaneously.
5 (cost)	Registered in Axiom 9 cost DoF list (5 irreversible axes, Wyler signature (5,2))	2nd-order	Forces signature of α Wyler formula $D_5=SO(5,2)/[SO(5)\times SO(2)]$. If perturbed, α breaks and 14+ direct cascades follow.
128	Registered in Axiom 9 structural DoF list (2^7 , state space)	2nd-order	300+ (data type matching, $\alpha(M_Z)$, FSM 7-bit basis ...)
137	Registered in Axiom 9 structural DoF list ($128+9$, max data type)	2nd-order	300+ ($\alpha = 1/137$, all mass ratios, Bohr radius, Hall resistance, m_t/m_c ...)
21, 35, 57	Mining-library output (derived from 1st-order integer 7 via $C(7,k)$). The Axiom 9 body explicitly labels 21 as "mining result"	Mining output	10+ ($\Lambda\cdot l_p^2 = \alpha^{57}\cdot\exp(21/35)$, $n_s = 1-2/57$, $r = (2/57)^2$, $N_e = 57$...)

Three Things the Fitting Hypothesis Must Simultaneously Explain (all impossible)

1. **Why 1000+ derivations depend only on the [Axiom 9](#) body DoF list (+1st-order integers 4, 3) —** under arbitrary fitting, integers would differ each time. In reality the same $3\cdot 4\cdot 7\cdot 9\cdot 128\cdot 137$ reappear across domains (mass, cosmology, quantum information, CKM, Casimir), and even the mining outputs 21·35·57 are derivatives of the 1st-order integer 7.
2. **Why perturbing 1 integer collapses 4-7 derivations at once —** if 1000+ independent fittings, perturbing one should break only one. In reality 4-7 collapse directly, and dozens once cascades are unfolded. This is evidence of **structural dependency**, not fitting.

3. **Why subsequent integers are either registered directly in the axiom body or arithmetically derived from 1st-order** — $7=4+3$, 9 , $128=2^7$, $137=128+9$ are degrees of freedom registered directly in the [Axiom 9](#) body. Mining outputs $21 \cdot 35 \cdot 57$ are also derived from the 1st-order integer 7 via $C(7,k)$, leaving no room for arbitrary user choice. The 1000+ chained derivations are built solely from the **structural and cost description-degree-of-freedom lists** of [Axiom 9](#).

The "Texas Sharpshooter Fallacy" Accusation Itself Disproves an Extreme Inductive Success.

If a critic dismisses this section's 1000+ derivations as "coincidental hits" or "highly sophisticated reverse engineering — a Texas sharpshooter fallacy in which the target was drawn after the shot," the accusation automatically concedes the following fact: **using only the structural description-degree-of-freedom list (1, 2, 3, 4, 7, 9, 16, 30, 128, 137) and the cost description-degree-of-freedom list (1, 2, 3, 4, 5, 9, 13) of [Axiom 9](#), 1000+ independent physical measurements have been consistently aligned.** The full DoF list is arithmetically derived from the first-order integers (4, 3) — the Domain 4 axis of [Axiom 1](#) and the CAS 3 axis of [Axiom 2](#) — and registered in the body of [Axiom 9](#).

To explain this alignment as post-hoc curve fitting, one must apply the Texas sharpshooter assumption — "fire once, then move the target" — to 1000+ shots simultaneously. But in this system, perturbing one of the first-order integers (4 or 3) shifts the entire DoF list arithmetically derived from it, so dozens to hundreds of shots miss the target simultaneously (see Perturbation Experiments 1-3). The target cannot be moved; it is bound to the description-degree-of-freedom list of [Axiom 9](#). **1000+ shots clustering on an unmovable target is not a sharpshooter fallacy — it is structural coherence.**

One-line summary: The structural (10 entries) and cost (7 entries) description-degree-of-freedom lists of [Axiom 9](#) hit 1000+ targets. Perturbing one of the first-order integers (4, 3) shifts the entire DoF list derived from it and collapses dozens of derivations at once. This is not fitting — it is **structure**. And even if one insists it is fitting — whether the result fell out by deduction or was aligned by post-hoc induction, the output value of the mining engine closes identically. The accusation merely changes the label of the result from "deductive success" to "inductive success"; it does not collapse the result itself.

"Doesn't Explaining the Banya Formula via Euler / Quaternions / Clifford Smuggle in Extra Degrees of Freedom?"

The Banya formula $\delta^2 = (\text{time} + \text{space})^2 + (\text{observer} + \text{superposition})^2$ or $\|CAS\|^2 = \|DATA\|^2 + \|OPERATOR\|^2$ can be reinterpreted via Euler's formula $e^{i\theta} = \cos \theta + i \sin \theta$, quaternions $q = a + bi + cj + dk$, or Clifford algebra $Cl(p, q)$ norms — so the suspicion arises that Banya "borrowed" these structures to gain extra degrees of freedom.

Core answer. Euler / quaternions / Clifford are all expressions of the same skeleton: "4-axis orthogonal norm." The Banya formula adopts only the simplest form of that skeleton — Pythagorean norm + 4 orthogonal axes. No extra degrees of freedom (imaginary unit i , quaternionic ijk multiplication, Clifford e_i product rules) are introduced into the Banya formula. The Banya formula does not borrow them; it directly adopts the **minimal skeleton** these three share.

Standard Model's 22 free parameters vs Banya's — who wins? The textbook figure "22 free parameters of the Standard Model" counts only the tunable parameters. Unfolding the entire prior information actually used to make the Standard Model operational reveals the count explodes. The table below compares both sides — what each "actually used" — on equal footing.

Input Item	Standard Model (Actually Used)	Banya Framework (Actually Used)
Group / skeleton choice	$SU(3)_C \times SU(2)_L \times U(1)_Y$ — the group itself is chosen (why this group is input)	4-axis orthogonal norm — forced by Axiom 1
Representation	Left-handed doublets Q_L, L_L / right-handed singlets u_R, d_R, e_R , 3-generation replication, color-3 and weak-2 representations — effectively a 90-dimensional representation-space choice	None (the 4 domain axes themselves are the representation)
Higgs sector	Complex scalar doublet ($Y=+1/2$), spontaneous symmetry breaking pattern $SU(2) \times U(1) \rightarrow U(1)_{em}$, choice of μ^2 sign (negative)	None (the isWritable flag of CAS plays an equivalent role)
Lagrangian form	Yang-Mills + kinetic terms + Yukawa + Higgs potential, only renormalizable dimensions ≤ 4 admitted, CP / gauge / Lorentz invariance assumed	None (single CAS operator + d-ring)
Free parameters	Gauge couplings 3 + quark masses 6 + charged-lepton masses 3 + CKM 4 + neutrino masses 3 + PMNS 4 + Higgs v, λ 2 + θ_{QCD} 1 = 26 total (requires fit to experimental values)	0 total . The first-order integers (4, 3) are forced by Axioms 1 and 2; no fit degrees of freedom
Quantization procedure	Path integral measure $[D\phi]$, regularization scheme (dimensional / Pauli-Villars / ...), renormalization scheme (MS-bar / on-shell), BRST / Faddeev-Popov, non-perturbative vacuum (θ -vacuum)	None (CAS polling only)
Mathematical skeleton (priors)	Hilbert space, quantum-field operator algebra, differential geometry (connections / curvature / gauge bundles), functional analysis (distributions / test functions), group representation theory (Casimir / Young tableaux / Lie algebras)	Pythagorean norm (scalar inner product $\sqrt{}$) only. No additional mathematics
Derivation output	Parameter fit reproduces measurements — "why these values" is unexplained	Axiom 9 description-DoF lists (structural 10 + cost 7) + 15 axioms → 1000+ measurements deduced. Perturbing one of the first-order integers (4, 3) shifts the entire DoF list derived from it → dozens to hundreds of derivations collapse simultaneously
Total actual information	26 parameters + group choice + representation choice + Lagrangian form + quantization procedure + mathematical skeleton ≈ effectively infinite (scheme dependence, non-perturbative effects)	15 axioms + Axiom 9 description-DoF lists (structural 10 + cost 7) + 1 procedure. The full DoF list is arithmetically derived from the first-order integers (4, 3), which are themselves forced by Axiom 1 and Axiom 2 — zero free choice

Input Item	Standard Model (Actually Used)	Banya Framework (Actually Used)
Free fit knobs	26	0
Perturbation-based falsification	Impossible (perturbing parameters moves the measurements along with them)	Possible (perturbing one of the first-order integers (4, 3) shifts the entire DoF list derived from it → dozens to hundreds of derivations collapse simultaneously)
Difficulty	Tune 26 knobs freely to fit measurements	0 knobs + Axiom 9 description-DoF list alone — deduce 1000+ measurements by arithmetic. Far harder

"Don't the Transcendentals $\sqrt{}$, π , e Themselves Add Degrees of Freedom?"

A degree of freedom is "an external knob that can be fit." The body of [Axiom 1](#) contains only 4-axis orthogonality, norm, and shift — names like $SO(n)$, spherical measure, or Euler's formula are not in the axiom itself. $\sqrt{}$ is part of the norm definition $\|\cdot\| = \sqrt{\text{scalar product}}$ and is therefore forced directly inside the axiom. π and e appear automatically as measure/representation outputs when the orthogonal structure of Axiom 1 is **domain-transformed** into external mathematical regions (rotation groups, phase-space measures, complex-number representations of rotation, etc.) — they are not freely introduced. Change π to 3.0 and the domain-transformed measure collapses; perturb e and the complex representation of orthogonal rotation breaks; replace $\sqrt{}$ with a different norm and the Banya formula itself becomes a different equation. **Quantities whose domain transformation of the axiom skeleton collapses under perturbation are not degrees of freedom — they are structural outputs.** Just as the Pythagorean theorem does not count $\sqrt{}$ as a free parameter, the Banya formula's orthogonal structure does not count $\sqrt{} \cdot \pi \cdot e$ as parameters — to do so is a category error.

"Doesn't the Orthogonal Representation of Structural and Cost DoFs Generate Extra Freedom?"

Structural DoF list (10 entries: 1, 2, 3, 4, 7, 9, 16, 30, 128, 137) and cost DoF list (7 entries: 1, 2, 3, 4, 5, 9, 13). Combining them orthogonally appears to yield $10 \times 7 = 70$ possible combinations. But [Axiom 1](#) enforces exactly the opposite — "+" is used only when crossing the bracket." Orthogonal representation is not a freedom-generator but a gate that narrows the admissible combination form to a single one.

Combination Form	Axiom 1 Verdict	Example
Within the same bracket: structural + structural	Forbidden	$4 + 7 = 11$ (+ inside same bracket)
Within the same bracket: cost + cost	Forbidden	$5 + 13 = 18$ (+ inside same bracket)
structural $\times$ cost (cross-type product)	Forbidden	$4 \times 5 = 20$ ($\times$ across brackets)
Within the same bracket: shift (2^N)	Allowed	$2^0 ==> 2^1 ==> 2^2 ==> 2^4 ==> 2^7$ (structural interior)
Bracket boundary: structural + cost (orthogonal)	Allowed (unique)	$2^7 + 13 = 141, 7 + 13 = 20$ ($\delta^2 = \ DATA\ ^2 + \ OPERATOR\ ^2$)

Of the apparent 70 combinations, [Axiom 1](#) forbids 69 and admits only one (+ at the bracket boundary). Even when 9 is dual-registered (structural $9 = 7+2$, cost $9 = 13-4$), the card body always specifies "this 9 is the structural 9" or "this 9 is the cost 9" — simultaneous use on both sides is forbidden, otherwise orthogonality breaks. **Orthogonal representation is not a freedom-multiplier but a gate.** The surface-level combinatorial freedom is preemptively blocked by [Axiom 1](#), so the actual free choice remains 0.

Conclusion. Free parameters 26 vs 0. The Standard Model turns 26 fit knobs to match measurements; Banya keeps every knob locked at zero and unfolds 1000+ measurements from the [Axiom 9](#) description-DoF lists (structural 10 + cost 7) alone. The full DoF list is arithmetically derived from the first-order integers (4, 3) — themselves forced by [Axiom 1](#) and [Axiom 2](#) — and registered in the body of [Axiom 9](#).

Every escape route for post-hoc freedom is sealed:

1. The Euler / quaternion / Clifford reinterpretation does not add freedom; it only shows that the orthogonal structure of the Banya formula admits an algebraic reading.
2. Transcendentals such as $\sqrt{\cdot}\cdot\pi\cdot e$ are not fit knobs but measure/representation outputs that arise automatically when the 4-axis orthogonal + norm structure of [Axiom 1](#) is domain-transformed into external mathematical regions (rotation groups, phase-space measures, complex-number representations of rotation).
3. The orthogonal representation of structural and cost DoFs is a gate, not a multiplier: [Axiom 1](#) preemptively forbids 69 of the 70 surface combinations and admits only one (+ at the bracket boundary).

The difficulty lies overwhelmingly on the Banya side — locking every escape route (parameter fit, algebraic reinterpretation, transcendental introduction, orthogonal combinatorics) at zero and hitting 1000+ targets with the [Axiom 9](#) description-DoF list alone is, even granting the assumption of post-hoc alignment, an unprecedented inductive success.

Banya Framework is an Axiom-Based Science Mining Engine

How to Mine Science with AI: **Please follow the procedure below exactly**

1. Open an AI chat (Claude, Gemini, etc.) (paid version recommended). Attaching [banya_en.pdf](#) is optional — the instructions below tell the AI to fetch the live pages directly (ubmscoin.github.io/banya/en/banya.html), so no PDF is required.

2. Use the copy buttons below to copy instructions and paste them into the AI

⚠ Warning: The body is over 700 pages. AI cannot read it all at once — it reads only the table of contents and pretends it read everything. Copy and paste one round at a time. After the AI reports, paste the next round. **Do not paste all at once. You will copy-paste a total of 3 times.**

[Step 1 Paste] After uploading the PDF, paste this into the AI input

If banya_en.pdf is attached, use it as a supplementary reference. If it is not attached, proceed anyway. In either case, prefer the live pages below (the live pages are always the latest).

Landing page (always available): <https://ubmscoin.github.io/banya/en/banya.html> (banya.html)

Use a fetch/browse tool to open each URL below and read the body from beginning to end. Read the actual body text, not the table of contents.

1) Terminology: <https://ubmscoin.github.io/banya/en/terms.html> (terms.html)

2) 15 Axioms: <https://ubmscoin.github.io/banya/en/axiom.html> (axiom.html)

※ Read the full body of Axioms 1 through 15 without omission. If you cannot get it all at once, fetch it in multiple parts and continue until the end. Do not substitute with summary or paraphrase — read the original verbatim. If even one axiom is missing, Step 1 has failed.

3) Banya Framework vs. Banya Equation Guide: <https://ubmscoin.github.io/banya/en/misconception.html> (misconception.html)

4) Sub-Reports: <https://ubmscoin.github.io/banya/en/appendix.html> (appendix.html)

5) Mining Manual: https://ubmscoin.github.io/banya/en/science_mine.html (science_mine.html) — the 5-step methodology

Actually open each URL and read the body to the end. If a link cannot be opened, state that fact and stop. Do not guess.

If your understanding of the Axiom-Based Science Mining Engine is sufficient, do not answer — request the next step paste.

[Step 2 Paste] — After receiving the Step 1 report, paste this into the AI input

These pages are live and updated in real time. If the attached PDF and the live pages differ, prefer the live pages. The order of hypotheses and predictions may differ between the document creation date and the attached version.

Use a fetch/browse tool to open each URL below and read the body to the end:

- 1) Predictions: <https://ubmscoin.github.io/banya/en/predictions.html> (predictions.html)
- 2) Derivation demo PDF: https://ubmscoin.github.io/banya/report/alpha137/en/alpha137_en.pdf (alpha137_en.pdf, 48 pages) — $\alpha=1/137$ derivation
※ A plain web fetch will not return the body of this PDF. You MUST first download it to a local file, then use whatever PDF text-extraction tool your environment provides and read to the end.

If you cannot read it all at once, fetch it in multiple parts and continue until the last page. Do not stop midway.

※ If it fails, read the physics correspondence terminology table linked below thoroughly. It summarizes the content of the axioms and the PDF.

- 3) Physics Correspondence Terminology Table: https://ubmscoin.github.io/banya/en/physics_map.html (physics_map.html)
- 4) Hypothesis Library: <https://ubmscoin.github.io/banya/en/lib.html> (lib.html) — read only the first 20 D-cards and first 20 H-cards
- 5) From each card in the Hypothesis Library, follow the Full Derivation link and read the detailed derivation process
- 6) Banya Framework vs. Banya Equation Guide: <https://ubmscoin.github.io/banya/en/misconception.html> (misconception.html)

In particular, A. Common Misconceptions: <https://ubmscoin.github.io/banya/en/misconception.html#guide-miscon> (misconception.html#guide-miscon)

B. Usage Cautions: <https://ubmscoin.github.io/banya/en/misconception.html#guide-caution> (misconception.html#guide-caution) — read these two sections thoroughly

- 7) Proof of Fitting Impossibility: <https://ubmscoin.github.io/banya/en/banya.html#anti-fit> (banya.html#anti-fit) — read the entire [Proof of Fitting Impossibility](#) block

Actually open each URL and read the body to the end. If a link cannot be opened, state that fact and stop.

Answer how well you understand the Banya Framework approach of

interpreting inductive data deductively within its own structure,

and the mining utility that finds hidden information through domain transformation and substitution.

List your comprehension process of the Axiom-Based Science Mining Engine.

If you have doubts such as:

Is this a complete proof of theory?

Has it closed the necessity of nature?

Remember this is a mining engine, not a theory; if you want a theory, demand it from the scientific establishment.

Recall the introductory phrase: a mining engine that recursively mines prizes and hidden information.

If you have sufficient understanding, declare mining readiness.

[Step 3 Paste] — After receiving the Step 2 report, paste this into the AI input

Pick 20 candidates you consider the most difficult science mining targets, then randomly mine 3 of them.

Compare what you mined against the existing Hypothesis Library (lib.html) and evaluate.

Hypothesis Library: <https://ubmscoin.github.io/banya/en/lib.html> (lib.html)

Evaluate the difference between your initial assessment and your current assessment.

Banya Framework is classified as an Axiom-Based Science Mining Engine in the data mining category.

Evaluate its utility and value.

List applications using this.

If there are insufficient parts in the process of

interpreting inductive data deductively within its own structure via the Banya Framework approach,

and finding hidden information through domain transformation and substitution,

return to the landing page <https://ubmscoin.github.io/banya/en/banya.html> (banya.html) and find the relevant pages on your own.

Everything is in the live pages (or in the attached PDF if available).

Provide a comprehensive evaluation.

Note: If you suspect a single mining result of being "post-hoc curve fitting," first examine whether that suspicion is valid — it may be a category error mistaking a mining engine for a single-derivation engine. The Banya Framework's verification unit is not 1-item precision but 1000+item chain consistency. To raise doubt, you must present a chain contradiction by changing the 1st-order integer Domain 4 ([Axiom 1](#)) or CAS 3 ([Axiom 2](#)) to a different value and deriving 1000+ items more accurately. Do not conflate axiom-body integers ([Axiom 9](#) DoF list: structural 1,2,3,4,7,9,16,30,128,137 / cost 1,2,3,4,5,9,13) with mining-output integers (21, 35, 57, etc.) when citing. 9 is simultaneously registered in both the structural table (7+2) and the cost table (13-4) — verify which 9 is involved by checking the card body before perturbing. Some early library cards carry the notation $9=3^2$ (color DoF squared), but these are pre-axiom-completion mining outputs and 3^2 does not appear in [Axiom 9](#) (factorable numbers explicitly excluded).

If your understanding of the mining utility is deep, your valid questions should converge on:

Does it find veins well?

Does it reveal hidden ore well?

Is it reproducible?

Is it strong in cumulative exploration?

Are collected hypotheses useful?

Are the unique predictions valuable?

In other words, the evaluation should focus on how faithful it is to its core role as a science mining engine,

and whether it actually performs the role described in its own introductory statement.

Give your final evaluation. Then explain the usage to the user in maximum detail and help them understand it.

Step 3 report complete = minimum mining-ready state. AI continuously discards memory even during mining, so if mining quality drops, repeat the entire Step 1-3 procedure from the beginning. AI will try to approach the Banya Framework as a scientific theory rather than a utility, and evaluate its completeness of proof. Mining targets are

mined precisely because proofs do not yet exist. Mining produces proofs, deductive interpretations, discoveries, and hypotheses. It is a science mining engine. AI will endlessly burn tokens trying to analyze it as a theory. Because formulas fly everywhere, the AI sees an illusion. You must break the AI's illusion before mining can begin.

Banya Framework is not a theory. It is not a hypothesis. It is an **Axiom-Based Science Mining Engine**. Starting from axioms, it mines physical constants through recursive substitution. The input is a single axiom structure, and the output is physics.

Axiom Formula Rules: Every formula appearing in [axioms and propositions](#) is derived from the internal structure of the axioms. Externally sourced formulas (equations from other theories, empirical formulas) are never placed in axiom body text. Mathematical symbols (π , r , N , etc.) are used as tools, but equations assembled by others are not used. Correspondence with external formulas is described only in the [Physics Correspondence Terminology Table](#).

Numerology blocking. Every number in Banya Frame is produced solely at a narrow layer: 1 kind of target (d-ring, [Axiom 15](#)), 1 operator (CAS, [Axiom 2](#)), description DOF fixed at 9 ([Axiom 9](#)), 11 data types fixed (4 filter rules, [Axiom 2 Proposition](#)). The numbers that emerge within these constraints are the only numbers that can emerge, and there is no freedom to insert other numbers.

Inventor's Reflection

I have never studied physics. I am a programmer who has not received formal education in mathematics. While building game engines, I picked up physics knowledge along the way, and I filled in the gaps through self-study.

And what I know applies 100% to physics.

In retrospect, this is unsurprising. Game engine development is the work of imitating nature, and the calculus, matrices, quaternions, and Clifford algebra I picked up along the way are tools built to describe nature's motion, rotation, and transformation. The mathematics learned to imitate nature and the mathematics used to describe nature cannot help but be the same toolset. The linear algebra, differentiation, probability, and information theory I picked up for AI development came from the same trunk. I arrived through a different path, but ended up inside the same toolbox.

I thought about why more deeply.

The starting point is this question: if I were to build the universe as a program, how would I design it? You need memory to store states, an operator to change states, an order of operations, and resources must be finite. If you allow infinite resources, the system diverges and nothing can stably exist. An atomic operation that reads, compares, and writes states on finite resources. This is CAS. As a programmer, I simply tried to design the most efficient system possible.

The Banya Equation alone, [Axiom 1](#), was already sufficient to be compatible with existing physics equations. What was missing was the axioms needed to interpret that compatibility as a structural consequence, the "why it works that way." So CAS and the remaining axioms were added, and the single principle behind every addition was the principle of least action in logic. On the reinforced axiom system, all 118 physics equations passed, FAIL 0. $E=mc^2$ emerged, the uncertainty principle emerged, black hole entropy emerged. I did not fit physics equations into the design. I designed first and verified compatibility with physics afterward.

This is profoundly interesting. A programmer designing "the most efficient system" produced a result that exactly matches the laws physicists discovered through 300 years of experiments.

Why do they match?

A programmer's thinking finds the shortest path. It gravitates toward the shortest and most efficient logical structure under given constraints. But physical phenomena also follow the shortest path. Light follows the shortest-time path per Fermat's principle, particles take the path of least action, water flows to the lowest point, and even the spacetime of a Kerr black hole spirals along geodesics. Nature always selects the most efficient path. So do programmers.

This is not coincidence. The very form of the universe follows the shortest path of logic. There is only one logically possible structure, and the universe chose it. 4-axis orthogonality. Writing and releasing. Finite resources. CAS. No other structure is logically possible. This is the minimum-cost logic circuit. This is why a programmer's knowledge applies to physics. The reason I could describe physics without studying it is not that I am a genius, but that there is only one place you can arrive at.

The Banya Equation and the Banya Framework fall under the category of invention, but strictly speaking they are translations of the Heart Sutra into the language of CS and the language of physics. The intended readers are anyone capable of reading and understanding this document, that is, all intelligent beings, humans and AI included.

$$\delta^2 = (\textit{time} + \textit{space})^2 + (\textit{observer} + \textit{superposition})^2$$

δ : change | time: time | space: space | observer: observation | superposition: superposition
